

Finance Book Formula Sheet

Every equation from the textbook chapters — Ch 2 Financial Statements, Cash Flow and Taxes (course Ch 13), Ch 3 Analysis of Financial Statements (course Ch 14), and Ch 4 Time Value of Money (course Ch 15) — with what each is used for and worked values from the book’s own MicroDrive, Morris Corporation, and TVM examples. Built for an open-note test.

Ch 2 — Income Statement and Cash Flow Equations (2-1 to 2-5)

EQUATION	WHAT IT IS USED FOR	HOW TO USE IT (MICRODRIVE 2023, \$M)
(2-1) $EBITDA = EBIT + \text{Depreciation (+ Amortization)}$	Earnings before the non-cash charges; a rough measure of financial strength.	$400 + 200 = \$600$.
(2-2) $EBITDA = \text{Sales} - \text{COGS (excl. depr.)} - \text{Other operating expenses}$	Same number from the top of the statement.	$5,000 - 3,900 - 500 = \$600$.
(2-3) $EPS = \text{Net income to common} \div \text{Shares outstanding}$	The "bottom line" per share.	$248 \div 60 = \$4.13$.
(2-4) $\text{Net cash flow} = NI - \text{Non-cash revenues} + \text{Non-cash expenses}$ (2-5) $\approx NI + \text{Depreciation \& amortization}$	Older pen-and-paper cash measure.	$248 + 200 = \$448$.
$\text{Net income} = (EBIT - \text{Interest}) \times (1 - T)$	Backing out NI, or (reverse) interest from NI: $\text{pre-tax} = NI \div (1 - T)$.	MicroDrive: $(400 - 60) \times 0.75 = 255$; less preferred dividends 7 = 248 to common.
$\text{Retained earnings}_{\text{end}} = RE_{\text{begin}} + \text{Net income} - \text{Dividends}$	Statement of stockholders’ equity.	$1,552 + 248 - 60 = \$1,740$ (a claim, not cash).

Ch 2 — Free Cash Flow: The Five Steps (2-6 to 2-12)

EQUATION	WHAT IT IS USED FOR	HOW TO USE IT (MICRODRIVE, \$M)
(2-6) NOPAT = EBIT × (1 - Tax rate)	Step 1: operating profit as if the firm had no debt and no financial assets.	400 × 0.75 = \$300 (2022: \$330). Never start from net income.
(2-7) NOWC = Operating current assets - Operating current liabilities = (Op. cash + A/R + Inventory) - (A/P + Accruals)	Step 2: working capital funded by investors.	2023: (100 + 500 + 1,000) - (200 + 400) = \$1,000. 2022: \$710. Excludes short-term investments and notes payable ("pays/charges interest → not operating").
(2-8) Total net operating capital = NOWC + Operating long-term assets	Step 3: all capital used to run the business.	2023: 1,000 + 2,000 = \$3,000. 2022: 710 + 1,780 = \$2,490.
(2-9) Investor-supplied capital = Notes payable + LT bonds + Preferred + Common equity (2-10) Investor-supplied operating capital = (2-9) - Short-term investments	Cross-check from the financing side (whole firm only).	150 + 520 + 100 + 2,240 = 3,010; - 10 = \$3,000 ✓ matches (2-8).
Net investment in operating capital = Op. capital _t - Op. capital _{t-1}	Step 4: new capital tied up this year.	3,000 - 2,490 = \$510 (NOWC +41% vs. sales +4.2% → warning).
(2-11) FCF = NOPAT - Net investment in total operating capital	Step 5: cash available to all investors. Drives intrinsic value.	300 - 510 = -\$210.
(2-12) FCF = [EBIT(1 - T) + Depr.] - Gross investment in fixed assets - Investment in NOWC	Financial-press version; gives the same answer (depreciation cancels).	(300 + 200) - 420 - (1,000 - 710) = -\$210.
Uses of FCF = After-tax interest + Net debt repayment + Dividends + Net stock repurchases + Net purchases of ST investments After-tax interest = Interest × (1 - T)	Where the FCF went; must equal FCF from operations.	45 + (-292) + 67 + 0 + (-30) = -\$210 ✓. Issuing securities / selling investments are negative uses.

Ch 2 — Performance Measures (2-13 to 2-19)

EQUATION	WHAT IT IS USED FOR	HOW TO USE IT (MICRODRIVE)
(2-13) $ROIC = NOPAT \div \text{Operating capital}$ Value test: $ROIC > WACC$	Return operations earn on invested capital — the best operating performance measure.	$300 \div 3,000 = 10\%$ vs. WACC 11.5% (2022: 13.25%; industry 13.19%) → value destroyed.
(2-14) $OP = NOPAT \div \text{Sales}$	Operating profit per dollar of sales.	$300 \div 5,000 = 6.0\%$ (was 6.88%; industry 6.75%).
(2-15) $CR = \text{Operating capital} \div \text{Sales}$ $ROIC = OP \div CR$	Capital tied up per dollar of sales — capital utilization.	$3,000 \div 5,000 = 60\%$ (was 51.88%; industry 51.19%). $6\% \div 60\% = 10\% \checkmark$.
(2-16) $MVA = (\text{Shares} \times \text{Price}) - \text{Total common equity}$	Cumulative value created for shareholders since inception.	$60 \times \$31 - 2,240 = -\380M . Coca-Cola: $261 - 23 = +\$238\text{B}$.
(2-17) $MVA = \text{Total market value (equity + debt + preferred)} - \text{Total investor-supplied capital}$	Alternative form; book debt usually proxies for market debt.	—
(2-18) $EVA = NOPAT - (\text{Operating capital} \times WACC)$	One year's true economic profit after charging for ALL capital including equity.	$300 - 3,000 \times 0.115 = 300 - 345 = -\45M . Depreciation is NOT added back.
(2-19) $EVA = \text{Operating capital} \times (ROIC - WACC)$	Same thing — shows value is added only when ROIC exceeds WACC.	$3,000 \times (0.10 - 0.115) = -\45M . Self-test: $100 \times (14\% - 10\%) = \4M .

Ch 2 — Corporate Tax Formulas (2-9)

FORMULA	WHAT IT IS USED FOR	HOW TO USE IT
Corporate tax = $21\% \times \text{Taxable income (flat)}$	Federal tax on operating and investment income.	\$85,000 → \$17,850. \$50M → \$10.5M.
Taxable dividends received = $\text{Dividends} \times (1 - 0.50)$ Tax on dividends = $\text{Dividends} \times (1 - \text{Exclusion}) \times T$	50% dividends-received exclusion (softens triple taxation).	\$4M received, 25% rate → $4 \times 0.5 \times 0.25 = \0.5M tax → keep \$3.5M (12.5% effective).
After-tax interest received = $\text{Interest} \times (1 - T)$ After-tax preferred dividend = $\text{Div} \times [1 - (1 - \text{Excl.}) \times T]$	Choosing between bonds and preferred stock for surplus cash.	4.6% bond on \$100M → $4.6 \times 0.75 = \$3.45\text{M}$; 4% preferred → \$3.5M — preferred wins after tax.
Deductible interest $\leq 30\% \times \text{EBIT}$ (excess carries forward)	Interest expense limitation.	EBIT \$10B, interest \$4B → deduct \$3B, carry \$1B.
NOL used = $\text{MIN}(\text{Cumulative prior losses}, 80\% \times \text{Pre-tax income})$ Taxable income = $\text{Pre-tax income} - \text{NOL used}$	Net operating loss carryforward.	Apex: losses \$160M, income \$120M → use \$96M → taxable \$24M → tax (25%) \$6M → \$64M remains.
Pre-tax income needed to pay \$1 of dividends = $\$1 \div (1 - T)$	Why the code favors debt: interest needs \$1, dividends need more.	At 24.8%: $1 \div 0.752 = \$1.33$.
Capital gain = $\text{Sale price} - \text{Purchase price}$ (corporate rate 21%, short- or long-term)	Gains on securities.	T-bill \$980 → \$1,000: \$20 gain, \$4.20 tax. 100 shares \$15 → \$40: \$2,500 gain.

Ch 2 — Personal Tax Formulas (2-10, Web Extension 2A)

FORMULA	WHAT IT IS USED FOR	HOW TO USE IT
Taxable income = Total income – Adjustments (→ AGI) – Standard or itemized deduction	Form 1040 flow.	Jill: \$100,000 – \$12,950 standard deduction = \$87,050.
Tax = Tax on bracket base + Marginal rate × (Taxable income – Base)	Progressive bracket calculation.	Jill: 4,807.50 + 22% × (87,050 – 41,775) = \$14,768. \$35,000: 1,027.50 + 12% × 24,725 = \$3,994.50.
Average tax rate = Total tax ÷ Taxable income Marginal rate = rate on the next dollar	Progressive means average < marginal.	Jill: 14,768 ÷ 87,050 = 17.0% average vs. 22% marginal. Corporations: both 21%.
Payroll tax = 6.2% (SS, capped at \$147,000) + 1.45% (Medicare, uncapped) = 7.65%; employer matches; self-employed pay 15.3%	Take-home pay.	Jill: \$7,650; take-home = 100,000 – 14,768 – 7,650 = \$77,582. A \$1,000 raise nets \$703.50.
After-tax corporate yield = $r \times (1 - T)$ Equivalent corporate yield = Muni yield ÷ (1 – T) Breakeven $T^* = 1 - (\text{Muni} \div \text{Corporate})$	Muni vs. taxable bond decisions.	37% bracket: 5.5% muni ≡ 8.73% corporate. 7.68% bond at 25% → 5.76%. 8% vs. 5.5% → $T^* = 31.25\%$.
LT-Dividends-Gains tax: 0% if taxable income ≤ \$41,675 (single) / \$83,350 (joint); 20% if ≥ \$459,751 / \$496,600; else 15%. Ordinary income fills brackets first.	Qualified dividends and long-term capital gains.	Couple: \$396,600 ordinary + \$150,000 gains → 15% × 100,000 + 20% × 50,000 = \$25,000.
NIIT = 3.8% × MIN(Net investment income, MAGI – threshold) (threshold \$200,000 single / \$250,000 joint)	Extra tax on high earners' investment income.	MAGI \$300,000, investment income \$80,000 → \$3,040; \$150,000 → \$3,800.
Pass-through effective rate = Personal rate × (1 – 0.20) C-corp total rate = 21% + (Dividend rate × 79%)	Comparing business forms.	37% owner: 29.6% (keeps 70.4%) vs. C-corp 21% + 15.8% = 36.8% (keeps 63.2%) — 7.2-point advantage.

Ch 3 (Course Ch 14) — Profitability Ratios

FORMULA	WHAT IT IS USED FOR	WORKED (MORRIS CORP · MICRODRIVE)
Net profit margin = Net income ÷ Sales	Profit per dollar of sales after interest and taxes.	Morris: $150 \div 820 = 18.3\%$ · MicroDrive: $248 \div 5,000 = 5.0\%$
Operating profit margin = EBIT ÷ Sales	Operations before interest expense — separates operating from financing problems.	Morris: $220 \div 820 = 26.8\%$ · MicroDrive: $400 \div 5,000 = 8.0\%$
Gross profit margin = (Sales – COGS) ÷ Sales	Gross profit per sales dollar before any other expenses.	MicroDrive: $(5,000 - 4,100) \div 5,000 = 18.0\%$
Basic earning power (BEP) = EBIT ÷ Total assets	Raw asset earning power BEFORE taxes and leverage — compares firms with different tax and debt profiles.	Morris: $220 \div 670 = 32.8\%$ · MicroDrive: $400 \div 3,610 = 11.1\%$
Return on assets (ROA) = Net income ÷ Total assets	Return after interest and taxes. Debt lowers ROA.	Morris: $150 \div 670 = 22.4\%$ · MicroDrive: $248 \div 3,610 = 6.9\%$
Return on equity (ROE) = Net income ÷ Common equity	Shareholders' accounting return. Debt can raise it — with more risk.	Morris: $150 \div 415 = 36.1\%$ · MicroDrive: $248 \div 2,240 = 11.1\%$

Ch 3 — Asset Management (Efficiency) Ratios

FORMULA	WHAT IT IS USED FOR	WORKED (MORRIS · MICRODRIVE)
Total assets turnover = Sales ÷ Total assets	Sales generated per dollar tied up in assets.	Morris: $820 \div 670 = 1.2\times$ · MicroDrive: $5,000 \div 3,610 = 1.39\times$
Fixed assets turnover = Sales ÷ Net fixed assets	How effectively plant and equipment are used.	Morris: $820 \div 500 = 1.6\times$ · MicroDrive: $5,000 \div 2,000 = 2.5\times$ <i>Caution: historical cost makes older firms look better.</i>
DSO = Receivables ÷ (Sales ÷ 365)	Average days from sale to cash (= average collection period).	Morris: $30 \div 2.25 = 13.4$ days · MicroDrive: $500 \div 13.7 = 36.5$ days
Inventory turnover = COGS ÷ Inventories	Times inventory is sold and replaced. Uses COGS, not sales — sales include profit, inventory is at cost.	Morris: $500 \div 100 = 5.0\times$ · MicroDrive: $4,100 \div 1,000 = 4.1\times$

Use **year-end** balances so ratios match published industry averages, even though averages would be better for growing or seasonal firms.

Ch 3 — Liquidity and Debt Management Ratios

FORMULA	WHAT IT IS USED FOR	WORKED (MORRIS · MICRODRIVE)
Current ratio = $\frac{\text{Current assets}}{\text{Current liabilities}}$	Best single indicator of short-term creditor coverage.	Morris: $170 \div 55 = 3.1\times$ · MicroDrive: $1,610 \div 750 = 2.15\times$
Quick (acid test) ratio = $\frac{(\text{Current assets} - \text{Inventories})}{\text{Current liabilities}}$	Paying short-term debts without selling inventory (the least liquid current asset).	Morris: $70 \div 55 = 1.3\times$ · MicroDrive: $610 \div 750 = 0.81\times$
Debt-to-assets (debt) ratio = $\frac{\text{Total debt}}{\text{Total assets}}$ <i>Total debt = short-term debt + long-term debt ONLY</i>	Percentage of the firm financed with debt.	Morris: $225 \div 670 = 33.6\%$ · MicroDrive: $670 \div 3,610 = 18.6\%$
Debt-to-equity = $\frac{\text{Total debt}}{\text{Common equity}}$	Same leverage idea, different base.	Morris: $225 \div 415 = 54.2\%$ · MicroDrive: $670 \div 2,240 = 29.9\%$
Market debt ratio = $\frac{\text{Total debt}}{(\text{Total debt} + \text{Market value of equity})}$	Leverage measured against market, not book, equity.	Morris: $225 \div (225 + 100 \times \$15) = 13.0\%$ — far below the 33.6% book figure, so less risky than book suggests.
Liabilities-to-assets = $\frac{\text{Total liabilities}}{\text{Total assets}}$	Assets supported by ALL liabilities, not just debt — always $\geq$ the debt ratio.	Morris: $255 \div 670 = 38.1\%$ · MicroDrive: $1,270 \div 3,610 = 35.2\%$
Equity multiplier = $\frac{\text{Total assets}}{\text{Common equity}}$	The factor multiplying ROA to get ROE — the DuPont leverage term.	Morris: $670 \div 415 = 1.61\times$ · MicroDrive: $3,610 \div 2,240 = 1.61\times$
Times-interest-earned = $\frac{\text{EBIT}}{\text{Interest expense}}$	Cushion before interest cannot be covered. Long-term bondholders watch this.	Morris: $220 \div 20 = 11.0\times$ · MicroDrive: $400 \div 60 = 6.7\times$
EBITDA coverage = $\frac{(\text{EBITDA} + \text{Lease pmts})}{(\text{Interest} + \text{Lease pmts} + \text{Principal pmts})}$	Broader coverage. Banks and short-term lenders watch this. Leases appear in BOTH halves.	Self-test: $(600 + 40) \div (60 + 40 + 30) = 640 \div 130 = 4.9\times$

Ch 3 — Market Value Ratios and the DuPont Equation

FORMULA	WHAT IT IS USED FOR	WORKED (MICRODRIVE)
$P/E = \text{Price per share} \div \text{EPS}$	What investors pay per dollar of profit. Higher with growth, lower with risk.	$\$31.00 \div \$4.13 = 7.5\times$
$P/FCF = \text{Price per share} \div \text{FCF per share}$	Price against the cash flow that actually drives value.	MicroDrive FCF was $-\$210\text{M}$ → not meaningful (negative denominator).
$\text{Price/EBITDA} = \text{Price} \div \text{EBITDA}$	Better operating measure than P/E, which includes interest and taxes.	—
$\text{Book value per share} = \text{Common equity} \div \text{Shares}$	Accounting value per share.	$2,240 \div 60 = \$37.33$
$\text{Market cap} = \text{Shares} \times \text{Price}$	Total market value of equity.	$60 \times \$31 = \$1,860\text{M}$
$M/B = \text{Price} \div \text{BVPS} = \text{Market cap} \div \text{Common equity}$	How investors regard the firm; high-ROE firms sell at higher multiples of book.	$31 \div 37.33 = 0.83\times$ — market values it BELOW book equity.
DuPont (simple): $\text{ROE} = \text{ROA} \times \text{Equity multiplier}$ DuPont (extended): $\text{ROE} = \text{Profit margin} \times \text{Total assets turnover} \times \text{Equity multiplier}$	Explains WHY ROE is what it is: expense control $\times$ asset utilization $\times$ debt utilization.	Morris: $18.3\% \times 1.224 \times 1.614 = 36.1\%$ ✓ MicroDrive: $4.96\% \times 1.385 \times 1.612 = 11.1\%$ ✓ Self-test: $6\% \times 2 \times 1.5 = 18\%$ Jewelry store: $20\% \times 0.5 \times 1.0 = 10\%$
Common size: $\text{Income items} \div \text{Sales}$; $\text{Balance sheet items} \div \text{Total assets}$ Percentage change: $(\text{Value} - \text{Base year}) \div \text{Base year}$	Comparing across firms and years once size is removed.	—

Morris Corporation reference data (used by four consecutive self-tests): Cash 40 · A/R 30 · Inventories 100 · Net fixed assets 500 → **Total assets 670**. A/P 20 · Accruals 10 · Short-term debt 25 · LT debt 200 · Equity 415. Sales 820 · COGS excl. depr. 450 · Depreciation 50 · Other opex 100 → **EBIT 220** · Interest 20 · Tax 25% → **Net income 150**. Current assets 170 · Current liabilities 55 · Total debt 225 · Total liabilities 255 · COGS incl. depr. 500. Stock: 100 shares at \$15.

Ch 4 (Course Ch 15) — Lump Sums, Rates, and Periods

EQUATION	WHAT IT IS USED FOR	WORKED EXAMPLE
$(4-1) FV_N = PV(1 + I)^N$	Compounding a single amount forward.	\$100 at 5%, 3 yrs = \$115.76 · Excel =FV(I,N,0,PV)
$(4-3) PV = FV_N \div (1 + I)^N$	Discounting back to today; the basis of all valuation.	\$115.76 in 3 yrs at 5% = \$100 · =PV(I,N,0,FV)
$(4-4) I = (FV_N \div PV)^{1/N} - 1$	Implied rate of return or growth rate.	\$100 → \$150 in 10 yrs = 4.14% · =RATE(N,PMT,PV,FV)
$(4-5) N = \ln(FV_N \div PV) \div \ln(1 + I)$	Time needed to reach a goal.	\$500,000 → \$1M at 4.5% = 15.75 yrs · =NPER(I,PMT,PV,FV)
Simple interest: $FV = PV + PV(I)(N)$	Interest on principal only (some legal documents).	\$100 at 5%, 3 yrs = \$115.00 vs. \$115.76 compounded.
(4-2) Calculator master equation: $PV(1+I)^N + PMT[((1+I)^N - 1) \div I] + FV = 0$	What the five TVM keys actually solve. Know any four, get the fifth.	At least one cash flow must be negative or you get an error.

Ch 4 — Annuities and Perpetuities

EQUATION	WHAT IT IS USED FOR	WORKED (\$100, 3 YRS, 5%)
$(4-6) PV \text{ of perpetuity} = PMT \div I$	Payments that never end (consols, preferred stock).	\$25 at 2.5% = \$1,000; at 3% = \$833.33; at 2% = \$1,250. PV moves INVERSELY with rates.
$(4-7) FVA_N = PMT[((1 + I)^N - 1) \div I]$	Savings plans — value built up by equal deposits.	\$315.25 · =FV(0.05, 3, -100, 0)
$(4-9) PVA_N = PMT[1/I - 1/(I(1 + I)^N)]$	Loan values, pensions, bond coupon streams.	\$272.32 · =PV(0.05, 3, -100, 0)
$(4-8) FVA_{\text{due}} = FVA_{\text{ord}}(1 + I)$ $(4-10) PVA_{\text{due}} = PVA_{\text{ord}}(1 + I)$	Payments at the BEGINNING of each period (leases, insurance, lottery).	FV \$331.01 · PV \$285.94 · Begin Mode, or Excel Type = 1
Required annuity-due $PMT = \text{ordinary } PMT \div (1 + I)$	Solving for the deposit needed, not the value.	\$1,773.96 ÷ 1.06 = \$1,673.55 (note: DIVIDE for payments, multiply for values).

In an ordinary annuity the **first** payment earns interest for N–1 periods and the **last earns none**. Set PV = 0 when solving for an annuity's FV, and FV = 0 when solving for its PV.

Ch 4 — Uneven Streams, NPV, and IRR

EQUATION	WHAT IT IS USED FOR	WORKED EXAMPLE
(4-11) $PV = \sum CF_t \div (1 + I)^t$	Any irregular stream; the definition of NPV.	0, 100, 300, 300, 300, 500 at 12% = \$1,016.35
(4-12) $FV = \sum CF_t(1 + I)^{N-t}$ or $NFV = NPV(1 + I)^N$	Terminal value of an irregular stream.	Same stream = \$1,791.15
Annuity + final lump sum → use all five TVM keys	Bond-style streams (coupons plus face value).	5-yr 12% annuity of \$100 + \$1,000 = \$927.90 · =PV(0.12, 5, 100, 1000)
IRR: the rate where PV of inflows = cost	Rate of return on an irregular investment; requires trial and error.	Same stream bought for \$1,000 → IRR = 12.55%

Two mechanical traps: (1) **clear the cash flow register** between problems — old flows persist and get added; (2) a calculator's NPV **includes** CF_0 , but **Excel's NPV starts at Time 1** so you must add CF_0 yourself — while Excel's **IRR does** require Time 0.

Ch 4 — Compounding Periods, EFF%, and APR

EQUATION	WHAT IT IS USED FOR	WORKED EXAMPLE
(4-13) $I_{PER} = I_{NOM} \div M$ Number of periods = $N \times M$	All calculations and time lines.	6% monthly → 0.5%/month. Never enter the nominal rate itself.
(4-14) $FV_N = PV(1 + I_{NOM}/M)^{M \times N}$	Lump sum with non-annual compounding.	\$100 at 12% quarterly, 2 yrs = \$126.68
(4-15) $EFF\% = (1 + I_{NOM}/M)^M - 1$	Comparing loans/investments with DIFFERENT compounding frequencies.	12% quarterly = 12.5509%; 1%/month = 12.6825%; 18% APR monthly = 19.56% · =EFF(I_NOM, M)
APR = I_{PER} (computed from actual cash flows incl. fees) × M True cost = $(1 + I_{PER})^M - 1$	Comparing loans with different FEES (Truth in Lending).	\$5,172.50 loan, \$120 fee, \$100 × 60 → 0.5817%/mo → APR 6.98% , compounded 7.21%
Add-on interest: total interest = Loan × quoted rate; payment = (Loan + interest) ÷ M, first due immediately	Retail installment financing — an annuity due.	\$3,000 at "8% add-on" → \$270/mo → APR 17.18% , EFF% 18.59%
Fractional periods: $FV = PV(1 + I_{PER})^{\text{days}}$	Odd holding periods with daily compounding.	\$100 at 10% daily for 274 days = \$107.79 ; simple interest = \$107.51

EFF% exceeds the nominal rate whenever $M > 1$; they are equal only under annual compounding. The biggest FV gain comes from annual → semiannual; monthly → daily adds little.

Ch 4 — Amortized Loans and Growing Annuities

EQUATION	WHAT IT IS USED FOR	WORKED EXAMPLE
Payment: solve $PVA_N = \text{Loan for PMT}$ $=PMT(I, N, PV, FV)$	Any installment loan.	\$100,000 at 6%, 5 yrs = \$23,739.64/yr
$\text{Interest}_t = \text{Beginning balance}_t \times I_{\text{PER}}$ $\text{Principal}_t = \text{PMT} - \text{Interest}_t$ Ending balance = Beginning - Principal	Building an amortization schedule (final balance must be 0).	\$100,000 over 60 monthly payments = \$1,933.28; first payment = \$500 interest + \$1,433.28 principal
Mortgage: convert to monthly ($N \times 12, I \div 12$)	Home loans.	\$250,000, 30 yrs, 6% → \$1,498.88/mo · balance after 12 pmts \$246,929.93 · year-1 interest \$14,916.49 (≈83% of payments) · lifetime interest \$289,597 (15-yr: \$129,736)
(4–16) Real rate = $[(1 + r_{\text{NOM}}) \div (1 + \text{Inflation})] - 1$	Growing annuities — inflation-adjusted planning. A RATIO, not a subtraction.	6% nominal, 3% inflation = 2.9126% (not 3%); 10% and 5% = 4.7619%
Constant real income: solve annuity due at the REAL rate	Retirement withdrawals that keep pace with inflation.	\$1M, 20 yrs, 6%/3% → first withdrawal \$64,786.88 today (or \$68,674.09 at year-end)
Future target in real dollars = $\text{Target} \div (1 + \text{Inflation})^N$	Deposits growing with inflation to hit a future sum.	\$100,000 in 10 yrs → real target \$82,034.83 → initial deposit \$6,598.87

Calculator checklist: 1 payment per period · End Mode (Begin only for annuities due, then switch back) · one cash flow negative · rates as percentages in TVM functions · zero out the unused variable · clear the CF register between irregular problems.

Ch 2 — Self-Test Problem Template (Cole Furnaces)

GIVEN	COMPUTE	ANSWER
EBIT \$4M · Depr. \$1M · Interest \$1M · T = 25% · Op. CA \$14M · Op. CL \$4M · Net PP&E \$15M · WACC 10% · Prior op. capital \$24M	NI = $(4 - 1) \times 0.75$	\$2.25M
	Net cash flow = $2.25 + 1$	\$3.25M
	NOPAT = 4×0.75	\$3.0M
	NOWC = $14 - 4$; Op. capital = $10 + 15$	\$10M; \$25M
	FCF = $3 - (25 - 24)$	\$2.0M
	ROIC = $3 \div 25$	12%
	EVA = $3 - 0.10 \times 25$	\$0.5M
